I claim:

- A method of configuring resources in an IA-32 computer, comprising:
 establishing a remap window at the top of physical memory, the remap window
 corresponding to a PCI memory address range below 4GB; and
 reporting to an operating system that a portion of the remap window is reserved, the
 reserved portion corresponding to an AGP aperture within the PCI memory
 address range.
- The method of claim 1, further comprising:
 reporting to the operating system that the remainder of the remap window is usable memory.

5

- 3. A method of configuring resources in an IA-32 computer, comprising:
- setting a REMAPBASE register to the top of physical memory, and a REMAPLIMIT register to the value in the REMAPBASE register plus the size of a PCI memory address range;
- determining a translated AGP aperture address corresponding to the lower end of an AGP aperture minus the address of the top of lower memory plus the value in the REMAPBASE register; and
- in response to queries from an operating system to a BIOS, reporting at least three memory ranges as follows: a first usable range beginning at 4GB and ending at the translated AGP aperture address; a reserved range beginning at the top of the first usable range and having a size equal to AGP aperture; and a second usable range beginning at the top of the reserved range and ending at the value in the REMAPLIMIT register.

- 4. A machine-readable storage or transmission medium containing code that, when executed on a computer, causes the computer to perform a method of configuring IA-32 computer resources, the method comprising:
- establishing a remap window at the top of physical memory, the remap window corresponding to a PCI memory address range below 4GB; and
- reporting to an operating system that a portion of the remap window is reserved, the reserved portion corresponding to an AGP aperture within the PCI memory address range.
- The storage or transmission medium of claim 4, wherein the method further comprises:
 - reporting to the operating system that the remainder of the remap window is usable memory.

5

10

- 6. A machine-readable storage or transmission medium containing code that, when executed on a computer, causes the computer to perform a method of configuring IA-32 computer resources, the method comprising:
- setting a REMAPBASE register to the top of physical memory, and a REMAPLIMIT register to the value in the REMAPBASE register plus the size of a PCI memory address range;
- determining a translated AGP aperture address corresponding to the lower end of an AGP aperture minus the address of the top of lower memory plus the value in the REMAPBASE register; and
- in response to queries from an operating system to a BIOS, reporting at least three memory ranges as follows: a first usable range beginning at 4GB and ending at the translated AGP aperture address; a reserved range beginning at the top of the first usable range and having a size equal to AGP aperture; and a second usable range beginning at the top of the reserved range and ending at the value in the REMAPLIMIT register.
